

ABSTRACT

A network configuration device or entity has control of defined management and security functions in the network, or in many embodiments, in a Fibre Channel fabric. The network configuration device may control many functions. Foremost, it may control the recognition, operation and succession procedure for network configuration entities. It may also control user configurable options for the network, rules for interaction between other entities in the network, rules governing management-level access to the network, and rules governing management-level access to individual devices in the network. In addition, the network configuration entity may exploit policy sets to implement its control.
